Abstract
Aim: The aim of this study is to examined the effect of the oral administration of puerarin on wound healing in diabetic rat.

Material and methods: Twenty-four rats were divided into three groups: Group 1 (n:8) non diabetic control (NDC), group 2 (n:8) diabetic control (DC), group 3 (n:8) diabetic puerarine (DP). Rats Group DC and DP were injected a single dose 200 mg/kg streptozin solution for diabet model. A full thickness linear incision was made in the paravertebral region of the rats and the wound edges were covered with a sterile plaster. In Group NDC and DC, rats were given saline solution for 7 days. In Group DP , rats were given 200 mg/kg puerarin with oral gavage for 7 days. All animals were euthanized at 7 days postoperative. Connective tissue volumes and new vessel formation were measured with stereological analysis

Results: Stereologic analysis showed that Group NDC and DP had significantly more connective tissue volume at 7 days compared with group DC. New vessel formation volumes were also significantly lesser in group DC. Connective tissue and new vessel volumes difference were not statistically significant between group NDC and DP.

Conclusion: Orally administered puerarin enhances new vessel formation and support wound healing in diabetic rats.

Keywords: Diabetes Mellitus; Puerarin; Wound Healing

INTRODUCTION
Diabetes mellitus is a disease affecting millions of people in worldwide and increasing day by day. Diabetes is a common disease characterized by elevated levels of free glucose as a result of diminished levels of insulin (1). In diabetes, the microvessels are damaged and the blood flow of the tissue decreases. In case of insufficient blood flow, there is a delay in wound healing with ischemic areas. In diabetic patients, ischemia related non-healing wounds can cause tissue or organ loss (2). Wound healing is a complex mechanism with different steps. Soft tissue healing has three phases such as inflammatory, proliferation and maturation. The problem that occurs in any of these phases may cause delay in wound healing. Inflammation, foreign body and systemic diseases such as diabetes can be among the reasons for delaying wound healing (3).

Delay in wound healing in diabetic patients may lead to major problems in oral and maxillofacial surgery. Soft tissue healing problems may negatively affect the operations such as grafting during implant surgery. Clinicians also investigated different methods to reduce the negative effects or complications of diabetes mellitus. Mostafavinia et al. examined the effects of photobiomodulation on tibial bone defect in streptozotocin (STZ)-induced type 1 diabetes mellitus in rats (4). Heshmati and Namazi reviewed effects of black seed on diabetes mellitus and metabolic parameters (5).

In Diabetes mellitus, addition to medical therapy, diet and alternative treatment methods may be used (6). Puerarin is isolated from the body of Pueraria lobata plant. It has been used for many years in alternative Chinese medicine. It ia a major isoflavone phytoestrogen that is used in a variety of medical situations due to beneficial effects such as vasodilatation, antioxidant, anticancer, anti-inflammatory, reducing fever, providing bone formation and decrease insulin resistance (7). Puerarin has been...
used in China for diabetes mellitus (DM) treatment since the early 1990s. Although studies showed that puerarin has positive effects on diabetes and also inhibits different diabetic complications (8,9), to our knowledge there is no study about effect of puerarin on soft tissue healing in diabetic rat model.

The aim of this study is to evaluate the effect of puerarin on wound healing in diabetic rat model.

MATERIALS AND METHODS

Animals and experimental design
This study was approved by the Animal Experimentation Committee of Bulent Ecevit University, Zonguldak, Turkey with a protocol number 2015-19-02/09. 6–8 week-old twenty-four rats were used in this study. Cages of all animals were in rooms with temperature of 22 ± 1 °C and humidity rate of 40–60%. Twelve h of day and 12 h of night standardization was configured by illumination system. Rats were divided into three groups. Group 1 (n:8) non diabetic control (NDC), group 2 (n:8) diabetic control (DC), group 3 (n:8) diabetic puerarin (DP).

Surgical procedure
Animal laboratory was used for surgical operations. Anesthesia was performed with intraperitoneal injection of 35 mg/kg ketamine hydrochloride (10% Ketaset; Richter Pharma AG, Wels, Austria) and 3 mg/kg xylazine hydrochloride (Rom-puns, Bayer, Leverkusen, Germany). Under sterile conditions, a full thickness linear incision was made in the paravertebral region of the rats. The wound edges were covered with a sterile plaster. All animals were sacrificed at day 7 after surgery. The wound area was examined by stereological analyses. In group DP, all rats were given 200 mg puerarin (diluted in distilled water) (99%) (Sigma-Aldrich, St Louis, MO) by oral gavage method for 7 days after diabetic model preparation.

Diabetic rat model
Diabetes was induced by a single intraperitoneal injection of Streptozocin (STZ) solution (200mg/kg). Rats were fasted for 16 hours prior to injection. Freshly prepared 0.1M Citrate buffer was added to streptozotocin powder (Sigma 85882) with final concentration of 20 mg/ml. On the first day of the injection the rats were fed with 10% sucrose. The next day rats were fed with fresh water only. Body weight and blood glucose were measured after injection at least once daily and if necessary, more frequent measurements were made. Blood glucose levels were measured by using tail vein and recorded with a blood glucometer and test strips (ACCU-CHEK Active, Roche Diagnostics, Mannheim, Germany). Rats with fasting glucose levels ≥16 mmol/L were considered diabetic.

Tissue Process and Stereological Methods
Samples were prepared using standard histological procedures. After fixation in 10% formalin for 10 days, the samples were gradually dehydrated in an ethanol series (70%, 80%, 96%, and 100%), placed in xylene for clearing, and then embedded in paraffin. The tissue blocks were sectioned at 5 μm on a microtome (Leica RM2255, Germany) and stained with hematoxylin-eosin. The sections selected and stained with hematoxylin and eosiin were photographed using a stereology analysis system (Stereoinvestigator 9.0; Microbrightfield, Williston, VT) and a light microscope (M4000 B; Leica Instruments) equipped with a digital color camera (Microbrightfield). The unbiased Cavalieri method was applied to the light microscopy images to stereologically estimate the volume of connective tissue and new blood vessel formation using point-counting test grids. The point density of the point-counting grids was designed to obtain an appropriate coefficient of error for the area of interest in the images of the serial sections. The grid, with its systematic array of points was placed randomly on the image shown on the screen of a personal computer. The coefficient of error and coefficient of variation were estimated according to the formula of Gundersen and Jensen (10).

Statistical Analyses
The Shapiro–Wilk test was used to evaluate the normal distribution of the data. The stereological data was analyzed with the Kruskal–Wallis non-parametric test followed by post hoc group comparisons with the Bonferroni-adjusted Mann–Whitney U test, after the normality test of the data failed. For the Bonferroni correction, a 1/4 0.05/3 1/4 0.016 was considered to indicate statistical significance. All tests were performed using SPSS ver. 19.0 (SPSS, Chicago, IL). P < 0.05 was considered to indicate statistical significance.

RESULTS
There was no wound dehiscence or wound infection in surgical site. All rats tolerated surgery and postsurgical period without complication.

Histological evaluation
In non-diabetic control group (NDC), almost completely re-epithelization was observed. Connective tissue and collagen formation was determined. Newly formed blood vessels were present in the wound site.

In diabetic group (DP), the incision line was detectable, no re-epithelization was observed. Inflammatory cells were observed with connective tissue. A small number of vascularization was observed in wound area.

In diabetic puerarin group (DPG), according to diabetic group more re-epithelization was observed. Infiltration cells were observed and the newly formed blood vessels were more than the diabetic group.

Stereological analysis
The connective tissue volumes for groups NDC and DP were 1.57 0.1 mm3 and 1.54 0.1 mm3 respectively. For both groups, it was a statistically significant difference between group DC with a mean connective tissue volume, 0.99 mm3 (p<0.05). Although connective tissue volume in group NDC was more greater than group DP, the difference was not statistically significant (Figure 1).

New vessel volume in groups NDC was 0.076 0.017 mm3 and it was superior than in group DP (0.075 0.009 mm3)
but the difference was not statistically significant (p 0.05).
In group DC mean new vessel volume was 0.044 ± 0.006
mm3 and it was significantly lesser than other groups
(Figure 2).

DISCUSSION
In our study, we hypothesized that oral administered
puerarin may have positive effect on angiogenesis and soft
tissue healing in diabetic rats. After linear paravertebral
incision, we applied sterile plaster on wound area and
administered puerarin by oral gavage method. The data
were analyzed by stereological methods.

We choose rat as an experimental model in our study.
There are some reasons to prefer rat model in animal
studies such as; physiologically similar to human, easy to
feed and it is cheap (11). Although different methods are
mentioned in literature to obtain the diabetic rat model,
STZ injection is the one of the most common method. In
literature there are different methods and doses for STZ
injection (12-14). We used Deeds et al. (14) method for
diabetic rat model preparation with a single dose of 200
mg STZ injection. Blood glucose measurement verified
the diabetic rat model.

In diabetic patients, although there are many
complications, one of the most important is impaired soft
tissue healing due to the micro deterioration of vascular
structure (2). Soft tissue healing is so important in oral
and maxillofacial surgery and directly affects the success
of operation. Especially in cases like dental implant
surgery or graft operations that primary wound healing
is important, inadequate soft tissue healing in diabetic
patients may lead problems (15).

Clinicians investigated different methods or agents
to prevent the adverse effects of complications in
diabetes patients. Hong et al. showed positive effect of
recombinant human epidermal growth factor on wound
healing in diabetic rats (16). Vascular endothelial growth
factor (VEGF) was used to treat wound healing in diabetic
rats. VEGF-treated wounds were observed early re-
epithelization and increased neovascularization (17).
Marston used Dermagraft for tissue engineering on soft
tissue healing in diabetes mellitus (18). Besides all these
materials or agents, herbal products have been used for
years on wound healing in diabetic patients. The minimal
toxic effects, less favorable side-effects and ease of
preparation are the main advantages of these products
(19).

In literature, there are studies that used different plant
products such as kaempferol, watercress and yerba mate
to reduce diabetic complications (20-22). We examined
the effect of puerarin on wound healing in diabetic rats.
Puerarin is isolated from the body of Pueraria lobata
plant. It has been used for many years in alternative
Chinese medicine (7). In literature, there are studies that
showed different beneficial effects of puerarin. Li et al.
(23) showed that intraperitoneal injection of puerarin
alleviated acute liver injury and reduced plasma alanine
aminotransferase and aspartate aminotransferase levels.
Yin et al. (24) investigated different doses of puerarin
on diabetic cardiomyopathy. 100 mg/kg and 200 mg/kg
puerarin have protective effect on diabetic cardiomyopathy
and inflammation. In another study, the effects of three
different doses of puerarin on atopic dermatitis were
examined. Results showed that puerarin has positive
effect on skin lesion by regulating different atopic and
inflammatory mediators (25). In our study, 200 mg/kg
puerarine were given by daily oral gavage method for 7
days. Puerarine dose was decided according to previous
study results that examined effect of puerarin in diabetic rats (24). According to our knowledge there is no study about effect of puerarin on soft tissue healing.

Stereological advantages over conventional histological examination methods and the most important of these advantages is inclusion of third dimension. This factor increases reliability (26). In our study we choose stereological methods for analyses of wound healing. According to stereological analyses oral puerarin reduced the negative effect of diabetes as similar to literature. Wound healing and newly formed blood vessel formation in the healthy control group were better than diabetic group using puerarin, but no statistically significant was found between them. When diabetic rat models were compared, it was observed that wound healing and new blood vessel values of puerarin group were significantly higher.

CONCLUSION

As a conclusion that orally administered puerarin has beneficial effects on wound healing in diabetic rats. Further investigations aimed at finding optimal doses and maximize the anabolic actions of puerarin on soft tissue are required.
